ATHANASIOS GOURDOMICHALIS
Java Programms
App1a.java
App1b.java

An integer greater than 1 is called a **prime number** if it has no divisors other than 1 and itself. For example, the number 17 is prime because it has no divisors other than 1 and 17. However, the number 91 is not prime as it is divisible by 7 and 13.

Write a program that:

1. Reads an integer from the user.
2. Checks whether the integer is a prime number using the **isPrime** method, which you must write. The method must take the integer as an **argument** and **return TRUE** or **FALSE** depending on whether the integer is prime or not.
3. Finally, the program will display an appropriate message (whether the integer is prime or not).

A. Complete the code in the **App1a.java** file so that the method **call** (in main) is made through an **object instance**.

B. Complete the code in the App1b.java file so that the method **call** (in main) is made statically, **without creating an object**.

Every program must compile and run from the command line (not through an IDE).
